## Summary

We show that for levels of Cumulative Singapore Mathematics experience (CSM) over the period 2002-09, students' scores increase with increasing CSM. For example, North Middlesex Regional School District (NMRSD) students who were $4^{\text {th }}$ graders in 2006 scored much better in 2008 as $6^{\text {th }}$ graders, relative to the overall Massachusetts (MA) student results that we use throughout for comparisons, and this despite the marked improvement over that period in MA student results.[1] Results for all grades 3 through 8 are included at the Singapore Mathematics Effects Between MA and NMRSD and the Singapore Math Effects Within NMRSD sections.

Multivariate and Repeated-Measures analyses strongly indicate a net positive effect of CSM on Massachusetts's Comprehensive Assessment System (MCAS) scores, both overall and by mathematics performance level; societal sub-groups are considered as well. These results are shown in Aggregate and Parallel Data beginning on page 17 and Multivariate Methods beginning on page 36. We speculate that performance gains due to Singapore math take time to develop, since the duration of participation in Singapore math classes has a greater positive impact on test score gains than participation at any given grade level or no participation at all. The most telling argument is at Table 18 on page 43 where we can clearly see the effect of CSM.

## Preface

The mathematics and science performance of students has been an increasing source of anxiety in America for some years. This unease has been reinforced by the Trends in International Mathematics and Science Studies (TIMSS: 1995, 1999, 2003) since they all showed U.S. students placing, internationally, within the "average" category; far below the "high performing" category dominated by Asian countries. ${ }^{1}$ The 1995 and later TIMSS examination of participating countries' mathematics curricula revealed that the high performing countries all shared a common, focused and coherent scope and sequence in their curricula. Since in this category only Singapore has English for its language of instruction ${ }^{2}$, Singapore's math curriculum and its textbooks received a good deal of interest here.

Eventually this interest led to the 2005 study funded by the U.S. Department of Education: "What the United States Can Learn from Singapore's World-Class Mathematics System (and what Singapore can learn from the United States)". [2] ${ }^{3}$ This

[^0]report presented comparisons of Singapore's Primary Mathematics (PM) textbook series with those of Scott Foresman and of Everyday Mathematics. The report also included a comparison of Singapore's $6^{\text {th }}$ grade assessment (Primary School Leaving Examination, PSLE) items with $8^{\text {th }}$ grade items from NAEP ${ }^{4}$ and from selected state tests, as well as Praxis ${ }^{5}$, again finding in Singapore's favor.

Meanwhile, largely through word of mouth, the hundreds of U.S. home schoolers using Singapore's Primary Mathematics textbooks have grown into thousands, but schools have been slower to adopt them. It is only within the last two years that a few school districts as well as a number of individual schools have begun implementing what is colloquially known as Singapore math (SM). But these implementations are recent, and cannot respond to the frequently heard question: These books do well in Singapore, but how do we know they will do well in the U.S.? It is to answer that question that the Gabriella and Paul Rosenbaum Foundation has undertaken this longitudinal statistical study of the North Middlesex Regional School District (NMRSD) in Massachusetts, the single school district whose Singapore math implementation is of long standing, having begun in the year $2000 .{ }^{6}$

## Acknowledgements

This study would not have been possible without the leadership and support of North Middlesex Regional School District's Superintendent, Dr. Maureen Marshall, who granted us access to the District's data. We also are indebted to Assistant Superintendent Dr. Deborah Brady for providing invaluable help and devoting so much of her time to the project. Special thanks are due to Dr. Mary M. Waight, Associate Superintendent (retired) for summarizing the District history with Singapore Math.

[^1]
## Singapore Mathematics Implementation at NMRSD

North Middlesex Regional School District (NMRSD) is a rural school district near the border between Massachusetts and New Hampshire, serving the towns of Ashby, Pepperell and Townsend. In response to poor student performance on state mathematics assessments, this district introduced a number of their teachers to the Singapore mathematics (SM) syllabus during a 2000 summer institute for pilot implementation that fall.

For effective implementation, new K-8 school curricula are most easily begun with K-1 or K-2, with another grade added each successive year. However, worried about their entering high school students' inadequate math knowledge, NMRSD chose to address these concerns with an SM pilot in their "feeder" middle schools (grades 5 to 8). The pilot program was quickly extended across classrooms and grades. Kindergarten was added in the 2002-03 year and, as can be seen in Table 1 on page 10 , every classroom in grades $1-6$ was using the SM curriculum by 2005-06. From this point on, Singapore math was established as the District's official curriculum.

At the same time that NMRSD was establishing the SM curriculum, Massachusetts was implementing higher standards statewide. It was crafting new mathematics standards (based in part on Singapore's) and toughening state tests as well as teacher certification requirements (most recently in 2009). Its schools have responded well and, overall, the State has had considerable success. Participating in TIMSS 2007 as a separate State, Massachusetts earned $5^{\text {th }}$ place overall, solidly ahead of most countries including the U.S. itself. Altogether, Massachusetts was providing a competitive base over the course of NMRSD's Singapore math implementation.

## SM Classroom Implementation

Since this study is focused on student outcomes, we do not attempt more than a brief outline of the mechanics of NMRSD's SM implementation.

The SM pilot began in the 2000-01 school year with the use of Singapore's Primary Mathematics, $3^{r d}$ Edition ${ }^{7}$ for grades 1-6 and the New Elementary Mathematics (Syllabus $D$ ) series for grades 7-8.

During the 2001-04 pilot years, students were assigned to SM teachers and nonSM teachers, respectively, by stratified random assignment. The goal was to achieve similar classroom enrollments, gender balances, and comparable proportions of special education and Title I students in each class.

[^2]Since SM instruction is cumulative, each grade builds on the preceding grades both in SM content and the special SM pedagogy including the "model method" for solving problems, which serves as a bridge to Algebra ${ }^{8}$. For students new to SM, teachers were responsible for providing support for any needed math "catch-up" as well as their own grade's math topics and pedagogy. During this pilot phase of SM implementation, teachers prepared special assessments twice a year that would identify for more attention those topic areas where student understanding seemed weak. Later, in 2007-08, common math assessments for grades 8-10 were implemented followed in 2008-09 by assessments for grades 1-6.

Setting the most effective curricular pacing was and remains a challenge, in part because the SM curriculum sequence is not fully aligned with the Massachusetts Standards. In order to cover topics examined for in the MCAS that are outside of the regular SM learning sequence, teachers developed and followed curriculum maps, usually looking to their pre-SM textbook material for supplementing SM. ${ }^{9}$

Initial teacher preparation for the SM pilot was arranged with nearby Worcester State College. Dr. Richard Bisk ${ }^{10}$ gave NMRSD's middle school teachers an intensive 10-day summer institute that was focused on the SM syllabus (math content) linked with the special SM pedagogy.

Part of NMRSD's plan for the institute was to develop their best teachers into "teacher leaders" who would then be designated to help district teachers polish their class-room SM-teaching. ${ }^{11}$ Three such teacher leaders did in fact emerge and for some years continued to play a large part in the district's SM implementation. ${ }^{12}$ With two additional teacher volunteers, these teachers taught the initial 6 SM classes.

Annual summer teacher workshops have continued to be the norm. In 2001, Dr. Bisk gave a 5-day SM program for teachers of grades 1-4, followed by a separate SM program for teachers of grades 4-10. The 2002 arrangement was somewhat different: two half-day meetings in the Spring, then 5 days in early August and a $6^{\text {th }}$ day meeting later in August. Other institutions covered professional development for NMRSD during 2003 to 2007 and, most recently in 2008 and 2009, Dr. Andrew Chen of Edutron gave an "intensive immersion institute" (boot camp) with SM components for NMRSD middle and high school teachers. Now during the 2009-10 school-year itself, math courses for grades 3-8 teachers are being offered.

[^3]After-school help for struggling students is known to be useful, but schools' ability to offer it depends on available funds. NMRSD's operational budget had only modest sums for such after-school and summer instruction but when such help is available, NMRSD notifies both those students and their parents by letter.

For 2000-04, each elementary school had $\$ 2000$ for after-school MCAS study, 2 days a week. Each middle school had $\$ 3000$ for before-school MCAS classes, for 2 days a week for 4 weeks. To this amount, state funds added $\$ 100$ per student per year, but in 2005 , state contribution was decreased to $\$ 20$ per student per year. Additionally, for under-performing high school students $\$ 15,000$ was allotted in 2006 and increased to $\$ 20,000$ in 2007.

Later, more targeted development was also put in place. In 2008, $\$ 24,000$ was allotted for developing a summer "bridge" math course for incoming 9 th graders who had struggled in $8^{\text {th }}$ grade. In 2009-10, double blocks of math have been added for "at risk" students in grades 9 and 10. Middle schools offered an MCAS academy for each grade level for 12 weeks before or after school. In the elementary schools, MCAS after school support was offered for struggling students. However, there continue to be no funds for extra positions of math specialist.

## Source/Verification of the Data Employed by the Study

The Singapore mathematics textbook series used by NMRSD schools differ from textbooks used in all other Massachusetts (MA) school districts. The State's student population at each grade is about 70,000 students, while NMRSD's is about 300 students. Thus, a reasonable approach in assessment of the effect of Singapore Mathematics (SM) on NMRSD students' is comparison of their mathematical performance with that of all of MA students. And since SM implementation took place over several years, it was also possible to compare SM versus non-SM student performance within the District itself, as well as with the state as a whole.

The Massachusetts Comprehensive Assessment System (MCAS) which evaluates student, school, and district mathematics performance is an ideal assessment tool. MCAS tests for mathematics are given in grades 3to 8 and 10. ${ }^{13}$

The Massachusetts Department of Education website contains and provides public access to an impressive amount of MCAS as well as demographic and sociological data at the overall state, district and school levels. Yearly MCAS Technical Reports are also issued, especially valuable for the researcher. However, individual

[^4]student data are sequestered from public access. It is for district use. The MA department of education has contracted with dataMetrics Software, ${ }^{\circledR}$ Inc. to make specialized software programs (the TestWiz ${ }^{\circledR}$ ) available to interface the MCAS with the District's own database. For example with TestWiz, teachers can call up students' MCAS results together with their attendance record for the current and/or past years.

Once given District permission to access individual student data, TestWiz enabled us to track individual students and their academic performance in mathematics during their years in District schools. However, at this point we discovered a fundamental shortcoming in the Massachusetts record-keeping system. It does not record the particular curriculum used in any subject. While math scores are available, the data collection system does not have the capability to record the textbook series in use. Thus, determining a student's Cumulative SM (CSM) exposure was a challenge.

Among the resources we used to track down the CSM of individual students, a table included in Dr. Mary Waight's testimony to the National Mathematics Panel was a useful guide. This illustrated the by-class and by-grade progression of Singapore mathematics implementation at NMRSD. We adapt a portion as Table 1, below.

| Table 1. Number of Singapore Math Classes at NMRSD |  |  |  |  |  |  |  |  |  |

Although Massachusetts electronic record-keeping of individual student MCAS scores was only put in place in 2003, NMRSD kept its own meticulous records for students in the SM pilot classes. This enabled us to obtain data for the 2001-02 year for SM classes, such as the MCAS scores for the pilot's $4^{\text {th }}$ graders. (NMRSD did not similarly keep individual MCAS data of their 2000-2002 non-SM classes.)

SM implementation extended as shown above in Table 1. Each grade-year with $100 \%$ SM classes adds a year to students' CSM. However, determining a student's CSM for grade-years when SM-participation was less than $100 \%$ was tricky. For each such grade year, Testwiz ${ }^{\circledR}$ extracted a list of all students in each instructor's class from the District databank. We then identified (from paper school records) all SM-teachers in each grade-year. Then, and only then, students (identified by their unique school IDs) who were in known SM-teacher classes could be assigned to SM experience for that grade-year ${ }^{14}$.

This roundabout method does have an advantage: it allowed us to find and count students' SM experience even for grade-years when no MCAS is given. A sample concatenated file for a student set counting $5^{\text {th }}$ grade $S M$ experience in this way (no MCAS for $5^{\text {th }}$ grade in that year) is shown at Table 2.

## Cohort - CSM data

We began evaluation of the effect of SM on NMRSD students' performance over time by choosing groups of students meeting three conditions.
(1) All of their test scores in Massachusetts's Comprehensive Assessment System (the MCAS) for 2002 through 2008 were available.

[^5](2) Their cumulative Singapore mathematics experience (CSM) over 3 or more years could be verified.
(3) All students within the group were in the same grade and school-year.

We call these groups of students cohorts or vectors. For example, the vector of the students who were in the $4^{\text {th }}$ grade in 2003-04 would be followed year by year through to $8^{\text {th }}$ grade in 2007-08.

For analysis we chose four such cohorts, V1 to V4, with over 1,000 studenttrials ${ }^{15}$ in each cohort. This provides for a very powerful study.

Note that MCAS results are not available for all grade years. Until 2001-02, only grades 4, 8 and 10 were tested; from 2002-03 on, grade 6 was also tested. Finally in 2005-06 MCAS began testing all grades 3 to 8 . Given the limited MCAS testing in years before 2005-06, the four cohorts we chose have the most complete data. Vectors are shown in Table 3 on page 14. Note, also:

1) While no MCAS was administered in $5^{\text {th }}$ grade in 2001-02 nor in $7^{\text {th }}$ grade in 2004-05, we do have cohort V1's SM exposure data for these years from NMRSD sources.
2) While $10^{\text {th }}$ grade results were available, the study did not include these in most of the analyses because SM was not used after $8^{\text {th }}$ grade. A number of graphs do include $10^{\text {th }}$ grade results, for completeness; see, for example, Figure 13 on page 49 .

## Parallel Groupings

Using the extensive NMRSD data to full advantage, we also examine for the relative math performance over classes, for example of students in 4th grade in 2004, in 2005, in 2006 and so forth. That is, these are different classes, in the same grade for different years; we call these groupings parallels.

## Categorical Data

We also examine MCAS results that are derived from the overall grade-year means ${ }^{16}$; measures of dispersion and reliability are reported in four categories (performance levels) for ranges of raw scores. This sort of categorization is used in Massachusetts and most other states: for MA the categories are "Advanced, Proficient, Needs Improvement, Warning/Failing". These categories provide easy iden-

[^6]tification of performance level, and allow for comparisons between individual student performance over time, and for groups by grade-year. Since MCAS provides the number of students in each of these categories for 1999-2009, categorical analyses were used over these years to compare MA and NMRSD performance by school-year, by grade-year, and by CSM exposure.

A later section that most directly addresses the effects of CSM exposure, Multivariate Methods, begins on page 36 .

## Methods

The MA and NMRSD test results are expressed as "mean scores". The scores themselves report the number of correctly answered test problems. Thus for grades 4 to 9 , the maximum MCAS score is 54 . However, in years when the maximum MCAS score differs from 54, we use "adjusted means" (or "standardized" or "scaled means"). For grade 3, where the maximum score is 40, scores are adjusted by the ratio 54/40. For most of this report Grade 10 is not reported; but grade 10's scores would be adjusted by 60/54.

When looking at results, it may be helpful for the non-statistician to see mean scores also in the form of percents. We call these "coded" means; a student score of 39 out of 54 MCAS problems would have $72 \%$ of the problems correct.

As described below, comparisons were carried out on both mean (or continuous) data and on categorical data. Both univariate and multivariate statistical methods were used, on MA versus NMRSD results and on within-NMRSD results. We also examined the effect on math results of sub-categories representing gender; generalized economic background of students; and whether students were enrolled in special education. In examining each year's mathematics performance, the study sought to determine whether continuing in SM over several years - that is, Cumulative Singapore Math (CSM) exposure - makes a difference. For this we relied on Multivariate, Repeated-Measure methods.

## Student Outcomes by CSM

## Continuous data

MA-MCAS results were gathered mostly from MCAS's annual Technical Reports [313]. MCAS data are reported for each tested grade in each school, in each District, and for the State as a whole. By NMRSD permission, MCAS data for their individual students (NMRSD-MCAS) was accessed via the TestWiz ${ }^{\circledR}$ facility.

In the Singapore Mathematics Effects Between MA and NMRSD section, beginning on page 22, analyses consisted of one-way analysis of variance (ANOVA), t-tests, means tests within NMRSD for continuous, or mean, data for the cohorts used in this study.
Multivariate measures also use cohorts or vectors of students over years at NMRSD and compare the cohorts' MCAS test results (mean scores) with the State's.

Table 3. Vectors are shown moving through grade-years. White cells represent grade-years with less than $100 \%$ of the classes receiving Singapore math instruction.

| YEAR | Grade |  |  |  |  |  |  |  |

## Cohort and Parallel Data

Using NMRSD's extensive data to good advantage, we also examine relative performance over classes, for example of students in $4^{\text {th }}$ grade in 2004, 2005, 2006 and so forth. These are different classes in the same grade for different years; we call these groupings parallels.

While the gaps in teacher-student information handicap a fuller investigation of some of our cohorts' relationship between CSM and math performance, we can use the parallel vectors to compare student performance by relative experience in SM instruction. For example, we have MCAS test data for $4^{\text {th }}$ grade from 1998 on. If we look at mean student performance in 2000-01, 2001-02, 2002-03, 2003-04 and thereafter (grouped), we may draw inferences from the differences in student performance that the parallel vectors highlight. While not individually related to student CSM, relationships will be suggestive of CSM exposure for the classes as a whole.

## Student Outcomes by Teacher

In addition to the curriculum used: a major, perhaps the major, determinant of student performance - besides aptitude and application - is the experience of the teacher in that curriculum. That effect may be expressed in various ways, but we chose to use student results by individual teachers' years of SM experience. Student results for individual teachers are shown at Figure 1. It is clear that teacher results vary considerably.

Mean MCAS score for all students taught by each teacher Grades 4 through 8

Figure 1. Student Results by Teacher.

We selected teachers who, in 2006, had between 0 and 5 years of experience with SM, and followed their students over parallels consistent with their experience. The measure of performance was mean student MCAS score over the period 20042007. These results are shown at Figure 2, below. The heavy, dashed red line indicates the MCAS mean score of NMRSD students overall Note that this is higher than the MA students' mean scores.

Figure 2. Mean Student MCAS Results by Years of Teacher Experience.
These figures show that there is great variability - often around $50 \%$ - in teachers' success with their students, whatever SM experience teachers had. (Notice the "belt" of each figure, their students' mean scores.) Confounding factors are too numerous and ill-understood to allow further clarification. (Note that teacher effects are also considered in the multivariate section of this report.)

## Aggregate and Parallel Data

One method of measuring the effect of SM over time is to review student MCAS scores for the same grade over the period of study available to us. Since SM was introduced in some classes and some grades over a period of years, students in later grades who had higher CSM might have different results. These differing results will help quantify the efficacy of SM.

For example, referring to Table 1, (page 10), $8^{\text {th }}$ graders in 2003-04 had 5/18 chances of being in an SM class and had $5 / 16$ chances in $7^{\text {th }}$ grade, $3 / 17$ chances
in $6^{\text {th }}$ grade and so forth. $8^{\text {th }}$ graders in $2004-05$ had approximately $6 / 18,7 / 17$, $7 / 17,5 / 17$ and 0 chances of being taught $S M$ since 2001 ; while $8^{\text {th }}$ graders in 2005-06 had a greater likelihood (14/18, 8/16, 9/17, 10/17 and $2 / 17$ ) of exposure to SM. MCAS scores may reflect the effects of SM exposure.

Figure 3 below shows these SM results overall for the different grade-years, while Table 4, beginning on page 19, shows individual SM student results. The trends are (with the exception of $4^{\text {th }}$ grade) positive over the study period. Comparing Grades 7 and 10 over years by ANOVA, we find they are significantly different (Levene's Statistic $1.267, \mathrm{P}=0.284$ and $\mathrm{F}=2.896$, df 3,1389 and $\mathrm{P}=0.034$ for $7^{\text {th }}$ grade and Levene's $0.758, \mathrm{P}=0.580$ and $\mathrm{F}=39.441$, df 5,1780 and $\mathrm{P}=0.000$ for $10^{\text {th }}$ grade). For the other grades, all Levene's Statistics suggest significant differences in variance.

The $4^{\text {th }}$ grade results are somewhat puzzling, but nevertheless follow the MA trend (see Figure 12 on page 48). Note that the same SM students who score poorly in $4^{\text {th }}$ grade in 2003-04 score higher than MA in $6^{\text {th }}$ grade in 2005-06, and that trend continues.

Results for regressions of CSM against MCAS Raw Mathematics Score each gradeyear for which we have test results are at Table 5, below. Please recall that only a very small portion of the variability in scores is accounted for by the regression generally about 5-10 percent. Two of the grade-years for which we have a good deal of data are not significantly different; these are $4^{\text {th }}$ and $6^{\text {th }}$ grades.

| Table 5. Regression for Grade by Year |  |  |  |
| :---: | :---: | :---: | :---: |
|  | Coefficient | t | P |
| Grade 3 | -.061 | -2.186 | .029 |

## Results

## Univariate Measures

We looked at Singapore Math effects between MA and NMRSD student' results and also within NMRSD's SM and non-SM students.

## Singapore Mathematics Effects Between MA and NMRSD

## Continuous Data

We first examined MCAS scores for NMRSD and for MA. Standardized grade means for MA and for NMRSD are compared in Figure 4, for the years 2003-2008. Note that on a grade basis, NMRSD scores are consistently higher, occasionally significantly so, for example, $3^{\text {rd }}$ grade.

Grade
$\square 3$
$\square 4$
$\square 5$
$Z 6$
$\square 7$
$\square 8$

Figure 4. MA versus NMRSD mean MCAS scores, by grade, averaged for years 2002-03 to 2007-08.

Other ways to view the same data are provided in Table 6 and in Table 9; there, the standardized mean and a coded, standardized mean are shown, respectively. Table 6 provides an additional measure: the difference between NMRSD and MA coded scores (i.e., NMRSD coded score minus the MA coded score). In all but three (of 33) grade-years, NMRSD scores were higher than MA scores. Figure 5 on page 24 shows this data graphically. Grade 10 is included for completeness.

|  | 4 | 38 | 71 | 38 | 70 | -1 |
|  | 5 | 35 | 64 | 37 | 68 | 4 |
|  | 6 | 36 | 66 | 39 | 71 | 5 |
|  | 7 | 33 | 61 | 37 | 68 | 7 |
|  | 8 | 34 | 62 | 36 | 67 | 5 |
|  | 10 | 35 | 65 | 40 | 74 | 9 |
| 2007 | 3 | 40 | 75 | 43 | 80 | 5 |
|  | 4 | 38 | 70 | 37 | 68 | -2 |
|  | 5 | 36 | 67 | 37 | 69 | 2 |
|  | 6 | 36 | 67 | 38 | 70 | 3 |
|  | 7 | 35 | 65 | 37 | 69 | 4 |
|  | 8 | 33 | 62 | 37 | 68 | 6 |
|  | 10 | 36 | 67 | 39 | 72 | 5 |
| 2008 | 3 | 41 | 75 | 48 | 90 | 15 |
|  | 4 | 37 | 68 | 36 | 67 | -1 |
|  | 5 | 36 | 66 | 36 | 66 | 0 |

| Table 6. Adjusted Mean and Coded Mean MCAS scores |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| by grade by year |  |  |  |  |  |  |
| Year | Grade | MA <br> Adjusted <br> Mean | MA <br> Mean <br> (coded <br> $54=100)$ | NMRSD <br> Adjusted <br> Mean | NMRSD <br> (coded <br> $54=100$ ) | NMRSD <br> minus <br> MA |
|  | 6 | 39 | 72 | 40 | 74 | 2 |
|  | 7 | 36 | 66 | 37 | 68 | 2 |
|  | 8 | 34 | 63 | 36 | 66 | 3 |
|  | 10 | 36 | 66 | 40 | 73 | 7 |

An ANOVA on these mean scores is significant ( $\mathrm{F}=11.406, \mathrm{P}=0.001, \mathrm{df}=1,64$ ) and this shows that, overall, NMRSD mean MCAS scores are significantly higher than those of Massachusetts for all grade-years for the 2003-2008 period.

Figure 5. Differences between NMRSD and MA Students' MCAS Coded Scores, 2002 to 2008

For the period 2003-2008, it is clear that NMRSD scores on the MCAS are regularly higher than MA's. A number of trends are apparent. As Figure 12 and Figure 13 (pages 48 and 49, respectively) also show, MA and NMRSD scores do seem to follow the same general upward trends: with $4^{\text {th }}$ grade scores the only exception.

While regression on the two sets of data pairs (MA mean and NMRSD mean) is significant (Adjusted $\mathrm{r}^{2}=0.626, \mathrm{~F}=54.626, \mathrm{P}<0.001$ ) this only reflects the trends we can see and does not connect them to a cause. Now we will pass to testing the contribution of Singapore Math to these results.

## Singapore Math Effects Within NMRSD

For Singapore Math's effects, we rely on the Vectors described in Table 3 on page 14 and in Cohort - CSM data beginning on page 11. Given the well-known complexity of factors bearing on student performance in testing, we could not expect to demonstrate significant differences in mean scores based just on univariate statistics. However, there are some suggestive findings, including some of those that led us to this study. Thus, it is useful to present our univariate results. For all students in the cohorts, Figure 6 below shows the relative frequency of MCAS Mathematics Raw scores (that is, how many students got a particular mean score) with and without Singapore Math experience for all scores in vectors V1 to V4. For the two data sets the medians are 37 and 39 , means are 35.58 and 37.33 for CSM $=0$ and CSM $>0$, respectively. Student's t is -4.142 (equal variances not assumed (Levene's $\mathrm{F}=4.151, \mathrm{p}=0.042$ ), df $838, \mathrm{p}=0.000$ ).

Frequency of MCAS Raw Scores with and without SM

Figure 6. Frequency of MCAS Raw Scores Without and With CSM for cohorts V1 to V4.

Figure 7 on page 28 below shows the effect of CSM on mean MCAS scores by grade. For example, grade 5 mean scores increase from about 35.5 to 37 to 38 for students with CSM's of 0, 1 and 2 years, respectively. Note that the figure reflects the MCAS testing history for grades; since MCAS testing of grade 5 only began in 2006, there are only the 3 years of CSM experiences applicable to $5^{\text {th }}$ grade MCAS scores in those academic years, i.e., 2005-2006, 2006-07 and 2007-08.

## Correlations

Since CSM is ordinal, a non-parametric measure of correlation, Spearman's rho, was used. For correlations, only complete Cohorts were analyzed; results for subsets of CSM (i.e., a subset of grades of SM experience) were not substantially different. Results for the Cohorts for MCAS scores ${ }^{17}$ are shown in Table 20; 4 of 7 are not significantly correlated. Note, however, that all the rho's are positive, i.e., MCAS scores rise with increased CSM exposure.

Correlations between CSM and the Social Parameters considered are presented in Table 21. The Free Lunch category (an indirect measure of family income) and Special Education are always significant. On the other hand, Gender (i.e., male, female) is not usually significant for all data in the Cohorts; the exceptions are in Cohort V1. Nevertheless, gender is significant for some grade-years, although there doesn't appear to be a pattern to this. Social Parameter comparisons are shown in Table 21, below.

## One-way ANOVA, t-tests and Regression

It is easy to show general improvement with increasing exposure to Singapore Math. For example, Table 8, below, shows t-tests by grade-year and for all the cohort V1, V2, V3 and V4 students; while Table 9 shows the relationship between CSM and student performance for all students, and for students in the Social Parameter sub-categories. By regression, for all students, these are significantly related (i.e., CSM may predict scores) ( $\mathrm{F}=7.767$, df $1,4,648, \mathrm{P}=0.005)^{18}$

MCAS Scores are significantly different ( $\mathrm{F}=7.244$, df 1,4,241, $\mathrm{P}=0.007$ ) for Free Lunch compared to those not receiving Free Lunch. In the same way, differences for Special Ed students they are also significant ( $\mathrm{F}=6.972$, df 1,587, $\mathrm{P}=.009$ ).

While the coded standardized mean scores may not appear different, they are, and CSM is a significant factor. The repeated measures dimension of these analyses are much more compelling. These are treated in the Multivariate Methods section beginning on page 36 .

[^7]

| :---: | :---: | :---: | :---: | :---: | :---: |
| Cohorts by SM experience |  |  |  |  |  |

ANOVA results for individual Cohorts are presented in Table 22 beginning on page 51 for all scores; in Table 23 beginning on page 53, for the Free Lunch categories; and in Table 24, beginning on page 54 for the Special Education categories.

In each of these, CSM categories with very low N's (low number of students) are excluded from analyses. For the raw scores, 1 of 7 comparisons is significant by ANOVA; for Free Lunch, 9 of 24 and for Special Ed, 1 of 11 are significant.
t-tests for all data for the various math sub-categories are shown in Table 10, below. In every case, mean scores for students with SM experience are higher than those with none. Note, also, that there are no more than 640 students with no SM math experience, pointing-up again the major problem with a study conducted on historical data.

Finally, t-tests on student results by socio-economic categories by SM are shown at Table 11. Again, all results for students with SM experience are higher, with the notable exception of Free Lunch-non-special Education students. A number of these results are significant, including all but 3 categories of Special Education students. Those were Free Lunch-Special Ed students for Math Raw, Pattern Recognition and Data, Statistics and Probability. It does appear from these that SM has generally had a beneficial result on students with disadvantages. It appears, as well, that the task of improving the results obtained by economically disadvantaged students may be somewhat more intractable than for Special Education students.

## Categorical Data - Both Between NMRSD and MA and Within NMRSD

Much of the available data on MCAS is in the form of categorical data, where students are assigned a proficiency category based on test results; the categories were described earlier. The great attraction is that we have data from 1998-2008, eleven years. These data for the period 1998-2008 are shown in Figure 8 where the difference (\%NMRSD students in category minus \%MA students in category) is plotted. It is clear that NMRSD students normally perform somewhat better than their statewide contemporaries. In Figure 8, while NMRSD's Advanced category is higher than that of MA in 3 grades, tied in one and lower in 3 other grades, NMRSD always has a higher proportion of students than does MA in the Proficient category. Likewise, NMRSD always has fewer students in the Failing category.

A word on interpretation: for the category differences, there are two "good" results. One, when NMRSD minus MA is positive, i.e., a higher proportion of NMRSD students are in the Advanced or Proficient categories. The other is at the other end of the spectrum, when NMRSD minus MA is negative, i.e., a lower proportion of NMRSD students are in the Needs Improvement or Failing categories. For this reason, each of the category graphs below are presented for all categories and also for the categories grouped as above, i.e., [Advanced and Proficient] and [Needs Improvement and Warning/Failing]. An example of this format is shown in Figure 10 on page 35. Again, we have included $10^{\text {th }}$ grade in this chart for completeness, since before 2006 MCAS tested only grades 4, 6, 8 and 10 .

Figure 8. Percentage of NMRSD students minus Percentage of MA students by Mathematics Proficiency Levels: by Grade

A look at MCAS results in years preceding SM implementation is informative, and MCAS mathematics results for 1998 are shown in Figure 9. These are typical for the period and examples for 1999, 2000, 2004 and 2008 are shown in Appendix 1 - Univariate Analyses beginning on page 47.

Figure 9. Differences, by Categorical Math Data, between NMRSD and MA in the 1998 MCAS.

This relation remains the norm for MCAS scores for the years 1998-2009. That is, both before and after the SM implementation, the proportion of NMRSD students with good proficiency levels is higher than that of their MA contemporaries.

Finally, Figure 14 on page 63 shows the relative percentage of students in the proficiency categories for NMRSD compared both to MA and to Quabbin School District, a district similar to NMRSD.

Figure 10. Aggregated Categories for MCAS Categorical Results, 1999.
Contingency table analyses for each grade-year for the SM vectors are presented in Table 25 in Appendix $3-x^{2}$ on categories on MCAS, beginning on page 64. While most of these are significant for grade-year and while mean scores uniformly rise with increased CSM, chi-square, regression and all other relational measures between category and CSM were almost never significant; $7^{\text {th }}$ grade in cohort V3 has, for example, $x^{2}=12.97$ (df 6, $\mathrm{P}=0.044$ ).

A number of suggestive trends are apparent, since with the exception of $4^{\text {th }}$ grade scores, MA and NMRSD scores do seem to follow the same general trends. NMRSD results are normally higher, see particularly Figure 12 and Figure 13 on pages 48 and 49 , respectively.

## Multivariate Methods

## INTRODUCTION

We utilized regression with either of two models for both SM and CSM: one relating only SM or CSM to MCAS scores (Model 1) and another relating SM or CSM, Teacher, Free Lunch and Special Ed and MCAS scores (Model 2). SM analyses were binary with SM either 0 or 1 for the particular student, grade-year and MCAS score. In addition, we utilized generalized linear modeling for multivariate and repeated measures analyses. We analyzed all cases. Note that vectors V1 and V4 are the only vectors that have sufficient range of CSM, including baseline no-SM grade-years that are necessary to allow meaningful analyses. These analyses are intended to describe the relationship of CSM to MCAS results. Only V1 is fully presented in this report; results for V4 are similar, keeping in mind that only one year in V4 has 0 SM and that for only about 80 students.

Significant results suggest that means for the MCAS scores were not the same for each level of the tested variable, i.e.,

$$
\begin{gathered}
\boldsymbol{H}_{\mathbf{0}}: \mu_{\text {teachers }_{a}}=\mu_{\text {teachers }_{b}} \\
\boldsymbol{H}_{\mathbf{0}}: \mu_{C S M_{0}}=\mu_{C S M_{1}}
\end{gathered}
$$

and so forth.

## Regressions MCAS Scores by SM for all data

For all data for Model 2, Free Lunch was $t=-8.563$ with coefficient -2.781 and $\mathrm{P}=0.000$, Special Ed was $\mathrm{t}=-35.902$ with coefficient -10.268 and $\mathrm{P}=0.000$, Teacher was $t=3.870$ with coefficient 0.008 and $\mathrm{P}=0.000$ and SM was $\mathrm{t}=3.729$ with coefficient 1.324 and $\mathrm{P}=0.000$.

Over the period 2002 - 2009, there are 114 teachers in the $1-8$ part of our data set, each of whom taught SM to as many as 429 students. To correct for teachers with only a few students, we also analyzed a subset of 44 teachers, each with more than 60 students. For this subset, Free Lunch was $t=-8.290$ with coefficient -3.102 and $\mathrm{P}=0.000$; Special Ed was -28.383 with coefficient -9.729 and $\mathrm{P}=0.000$; and Teacher was $\mathrm{t}=2.218$ with coefficient 0.006 and $\mathrm{P}=0.027$.

Data for teachers with >60 students by SM is presented at Appendix 2 - Individual Teacher Results, General Linear Model beginning on page 64. For these data and this model, SM had a positive effect on MCAS raw scores - students with no SM had mean scores 1.309 points below students with SM. Students in the Free

Lunch program scored 3.033 points below those not in the program and special education students scored 9.717 points below those not in special ed. Most teacher results were also negative. Reflecting the coding (no $\mathrm{SM}=0$ and $\mathrm{SM}=1$ ), most teacher coefficients are negative - i.e., MCAS raw scores for these teachers are higher than the No-SM mean MCAS score.

## Regressions MCAS Scores by CSM for vector 1-4

For Model 1 for all vectors, the CSM t-score was 2.231 with coefficient 0.200 and $\mathrm{P}=0.026$. The known CSM range for the period analyzed was $0-6$, though the nominal CSM for 2002-2009 could have ranged from 0-8.

For V1, Model 2, the CSM $\mathrm{t}=3.729$ with coefficient 1.324 and $\mathrm{P}=0.000$; Special Ed $\mathrm{t}=-8.760$ with coefficient -11.212 and $\mathrm{P}=0.000$; Free Lunch $\mathrm{t}=-8.760$ with coefficient -4.093 and $P=0.000$ while Teacher $t=3.870$ with coefficient 0.08 and $\mathrm{P}=0.000$.

For V2, CSM is without baseline, i.e., there are no non-SM scores.
For Model 2:
For 2006 Free Lunch $\mathrm{t}=3.827$, coefficient 5.499 with $\mathrm{P}=0.000$; Special Ed with $\mathrm{t}=-$ 4.832, coefficient -7.7023 and $\mathrm{P}=0.000$ then Teacher $\mathrm{t}=3.049$, coefficient 1.262 and $\mathrm{P}=0.002$.
For 2007, Free Lunch $\mathrm{t}=2.869$ with coefficient 4.816 and $\mathrm{P}=0.004$; Special Ed $\mathrm{t}=-$ 4.937, coefficient -8.541 and $\mathrm{P}=0.000$ and Teacher $\mathrm{t}=-3.452$, coefficient -0.707 and $\mathrm{P}=0.001$.
For 2008, Free Lunch $\mathrm{t}=3.679$, coefficient 6.884 and $\mathrm{P}=0.000$, Special $\mathrm{Ed} \mathrm{t}=-5.341$ with coefficient -10.793 and $\mathrm{P}=0.000$ and, finally, Teacher $\mathrm{t}=0.361$ with coefficient 0.075 and $\mathrm{P}=0.718$.

For V3, all SM are "yes" so we have no baseline; there are no Free Lunch data for 2006 and there are no Teacher data for 2008, so the models are different each year; Special Ed and Teacher for 2006, Model 2 less CSM for 2007 and Special Ed and Free Lunch for 2008. The results are $t=-5.446$ with coefficient -9.023 and $\mathrm{P}=0.000$ for Special Ed and $\mathrm{t}=4.029$ with coefficient 1.230 and $\mathrm{P}=0.000$ for Teacher.
For 2007 Special Ed is $\mathrm{t}=-3.904$, coefficient $=-5.374$ and $\mathrm{P}=0.000$; Free Lunch is $\mathrm{t}=3.479$, coefficient 4.134 and $\mathrm{P}=0.001$.
Note that here in 2007, Teacher $\mathrm{t}=-1.464$, coefficient -0.149 and $\mathrm{P}=0.144$, and is the only instance where Teacher was not a significant factor.
Finally, for 2008 , Free Lunch $t=4.438$, coefficient 5.482 and $\mathrm{P}=0.000$ and Special Ed $\mathrm{t}=-4.470$ with coefficient -6.502 and $\mathrm{P}=0.000$; there are no Teacher data for 2008.

V4 is, like V1, a vector for which we have better data, that is, data with few elisions.
For Model 2:
In 2005, CSM had $t=-1.054$ with coefficient -1.289 and $P=0.293$; Free Lunch $\mathrm{t}=$ 2.087, coefficient 3.158 and $P=0.038$; Special $\mathrm{Ed} t=-9.428$, coefficient -14.130 and $\mathrm{P}=0.000$; and, finally, Teacher $\mathrm{t}=-0.639$, coefficient -0.103 and $\mathrm{P}=0.524$. In 2006, CSM was $\mathrm{t}=-3.133$ with coefficient -4.129 and $\mathrm{P}=0.002$; Free Lunch $\mathrm{t}=$ 2.917, coefficient 5.20 and $\mathrm{P}=0.004$; Special $\mathrm{Ed} \mathrm{t}=-7.403$, coefficient -12.569 and $\mathrm{Pe}=0.000$; and Teacher $\mathrm{t}=0.050$, coefficient 0.007 and $\mathrm{P}=0.961$.
In 2007, $\mathrm{CSM} \mathrm{t}=-1.059$ with coefficient -1.495 and $\mathrm{P}=0.291$; Free Lunch $\mathrm{t}=$ 1.898 , coefficient 2.919 and $\mathrm{P}=0.059$; Special $\mathrm{Ed} \mathrm{t}=-8.699$, coefficient $=-12.954$ and $\mathrm{P}=0.000$; and Teacher $\mathrm{t}=2.559$, coefficient 0.448 and $\mathrm{P}=0.011$.
In 2008, we have no Teacher data but CSM $t=0.791$ with coefficient 0.858 and P $=0.430$; Free Lunch $\mathrm{t}=2.194$, coefficient 3.393 and $\mathrm{P}=0.029$ and Special Ed $\mathrm{t}=-$ 8.358, coefficient -12.524 and $\mathrm{P}=0.000$.

For $2009, \mathrm{CSM} \mathrm{t}=1.493$ with coefficient 1.933 and $\mathrm{P}=0.137$; Free Lunch $\mathrm{t}=$ 2.093, coefficient 3.882 and $P=0.038$; Special Ed $t=-7.368$, coefficient -13.297 and $\mathrm{P}=0.000$; and Teacher $\mathrm{t}=-1.534$, coefficient -0845 and $\mathrm{P}=0.127$.

## General Linear Model for Multivariate statistics

## All Cases

For all data, about 14,036 data points from 2002 to 2009 , we used a binary representation of SM, i.e., either yes or no. In the analyses we compared MCAS raw scores for math and the five other sub-categories of mathematical understanding in the MCAS lexicon: Number Sense, Pattern Recognition, Geometry, Measurement and Data, Statistics and Probability. Results for this analysis are shown at Table 12 and Table 13, below. For these analyses the model has the MCAS subcategories above as dependent variables and the model effects are Intercept + SM + teacher + Free Lunch + Special Ed + Free Lunch * Special Ed. As may be seen, with the exception of the cross-product of Free Lunch and Special Ed.; all the effects are significant.

For all cases: only a relatively small proportion of the variability of the results can be associated with the model effects; $\mathrm{R}^{2}$ 's range from about 0.10 to 0.20 . While this is to be expected in such large, amorphous data sets, we believe that diachronic analyses may provide more substantive suggestions of relationships. See also Individual Grade-Years on page 43 for an example of the difficulties with this.

## V1-4th grade 2002 - 8th grade 2008

## Multivariate Analyses

For V1 the model for multivariate analyses is 04_2002_Math_Raw_Score, 06_2004_Math_Raw_Score, 08_2006_Math_Raw_Score with 06_2004_CSM, and 08_2006_CSM (where for example 04_2002 refers to $4^{\text {th }}$ graders tested in 2002). Results are shown in Table 14 and Table 15, below. Table 14 gives the Wilk's Lambda for the effect (CSM) for V1 and, while all but 4th grade in 2002 are "significant", these analyses, again, do not account for most of the variability in the data sets - the partial $\eta^{2}$ translate to $R^{2}$ 's of about $0.2,0.005,0.06$ and 0.095 for the three levels of CSM.

| Table 14. Multivariate tests for V1 |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Effect |  | Value | F | Hypo- <br> thesis <br> df | Error df | Sig. | Partial <br> Eta <br> Squared |
| Intercept | Wilks' <br> Lambda | 0.815 | 22.701 | 3.000 | 301 | 0.000 | 0.185 |

Table 15 shows the effects of CSM on the Math Raw Scores for V1. Again, while "significant" the $8^{\text {th }}$ grade, results still suffer from the high residual sum of squares problem where little of the variability in the data are accounted for by the model.

## Repeated measures

For these analyses, we use Math Raw scores for $4^{\text {th }}, 6^{\text {th }}$ and $8^{\text {th }}$ grades as the measure and CSM for the between-subjects factors, or $4^{\text {th }}$ grade (2002), $6^{\text {th }}$ grade (2004) and $8^{\text {th }}$ grade (2006) Math raw scores by $4^{\text {th }}$ grade, $6^{\text {th }}$ grade and $8^{\text {th }}$ grade CSM. The results for these are similar to the preceding, with very large residual sums of squares limiting our confidence in the significance of the results.

| Table 16. Repeated-measures tests V1 |  |  |  |  |  |  |  |

Table 17 shows the Levene's test for the equality of error variances; in this case, since none are significant, we cannot say that variances are different from one other, and we may place some reliance on differences and allow ourselves to look at the means for each of the test years by CSM.

| Table 17. Levene's Test of Equality of Error Variances |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | F | df1 | df2 | Sig. |  |
| $4^{\text {th }}$ grade Math Raw Score | 1.719 | 10 | 296 | .076 |  |
| 6th $^{\text {th }}$ grade Math Raw Score | .886 | 10 | 296 | .546 |  |
| 8th $^{\text {th }}$ grade Math Raw Score | 1.167 | 10 | 296 | .313 |  |

In Table 18 we can see the cumulative effect of SM on mean MCAS Raw scores; results for sub-categories are similar. To illustrate the table, we'll look at a couple of examples.

1) For $4^{\text {th }}$ grade MCAS Raw scores, students with no SM had a mean score of 25.5 in $4^{\text {th }}$ grade, 21.8 in $6^{\text {th }}$ grade and 19 in $8^{\text {th }}$ grade.
2) Students with no $S M$ in $4^{\text {th }}, 5^{\text {th }}$ and $6^{\text {th }}$ grade but $S M$ in $7^{\text {th }}$ and $8^{\text {th }}$ grades had a mean score of 34.4 in $4^{\text {th }}$ grade, 39 in $6^{\text {th }}$ grade and 37 in $8^{\text {th }}$ grade. In addition to the effect of CSM, this shows how the propinquity in time of SM affects results. This is reinforced by the results of students with 1 year of $S M$ by $6^{\text {th }}$ grade and 3 years of $S M$ by $8^{\text {th }}$ grade (i.e., $S M$ in $7^{\text {th }}$ and $8^{\text {th }}$
grades) with MCAS mean score of 37.1 in $4^{\text {th }}$ grade, 40.5 in $6^{\text {th }}$ grade and 39.9 in $8^{\text {th }}$ grade.
3) A final example - the students with SM in each year, i.e., $4^{\text {th }}$ through $8^{\text {th }}$ grades, had means of 44.6, 43.9 and 44.8.

These results clearly show the effect of CSM over the period covered in the vector V1.

## Individual Grade-Years

The difficulty of post-hoc analysis of historical data is illustrated by Table 19 which shows results for $6^{\text {th }}$ grade in 2005. The Model is CSM+MCAS Raw score +
each of the sub-categories of MCAS Math. While the model as a whole accounts for much of the variability in the set - illustrated by the $\mathrm{R}^{2}$ - CSM and the other factors are much less reliable as predictors. For example, the sum of squares (Type III) for CSM is 2,614 and the error ss is 26,495 for this model and gradeyear.

| Source | Dependent Variable | df | Mean Square | F | Sig. | $\mathrm{R}^{2}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Categorical Data

The following figures and tables relate to the comparison of categorical data, largely the "Proficiency Categories" of the MCAS.

## Graphs of Categories: NMRSD-MA percents of students

The following graphs are the percentage of students in each category from NMRSD minus the percentage of students in the corresponding category from MA state results. In other words, if $20 \%$ of NMRSD students were in the Advanced category in grade 5 for 2007 while MA had $14 \%$ of their students in the Advanced category, the difference for that category for that year was $6 \%$.

The following are the bar colors for the proficiency categories used in MCAS. These are used in the graphs in this section.

For the grouped categories:

Advanced and Proficient
Nl and Failing

The 2008 graph for \%NMRSD students minus \%MA students, above, seems to suggest that either MA students are improving or that NMRSD students are worsening. We have seen that this is not the case when we consider mean scores, and the same is true when we look at the paired categories, Advanced plus Proficient and the Needs Improvement plus Failing.

Figure 14. MA, NMRSD and Quabbin Mean MCAS Percent in Proficiency Categories, 1998-2008.

Quabbin School District is near NMRSD and similar demographically. The categorical comparison we carried out in Figure 14, above, again shows NMRSD students achieving better results. There is little to suggest that further analysis would be informative; Quabbin students continue to improve over the period, as do NMRSD and MA.

## Appendix 2 - Individual Teacher Results, General Linear Model

Dependent Variable: MCAS Raw Mathematics Score

Model: (Intercept) + SM + teacher + Free Lunch + Special Ed

The coefficient indicates the direction and amplitude of the effect of the particular teacher and other model effect on MCAS scores.

Here, it may be appropriate to quote from the remarks of Dr. Mary Waight, NMRSD Associate Superintendent (retired), to the National Math Panel in 2006:

Improving outcomes for students in mathematics is dependent on a number of factors, chief among them a teacher with a strong math background, ongoing professional development, administrative support and involvement, and a mathematics program that encourages mathematical understanding.[14]

[^0]:    ${ }^{1}$ The 1995 and 2003 TIMSS ranked Singaporean $5^{\text {th }}$ and $8^{\text {th }}$ graders first in the world for math. Top TIMSS rankings: 1995, Singapore, South Korea, Japan, Hong Kong. 2003, Singapore, South Korea, Hong Kong, Taiwan.
    ${ }^{2}$ Singapore's primary languages are English, Standard Mandarin (or Standard Chinese), Malay and Tamil.
    ${ }^{3}$ http://www.air.org/news/documents/Singapore\%20Report\%20(Bookmark\%20Version).pdf

[^1]:    ${ }^{4}$ http://en.wikipedia.org/wiki/National Assessment of Educational Progress
    ${ }^{5}$ Praxis, one of a series of teacher certification exams written and administered by the Educational Testing Service (ETS). Various Praxis tests are usually required before, during, and after teacher training courses in the U.S. To be certified to teach in most U.S. states, one must earn qualifying scores on all parts of the Praxis I and certain Praxis II Content Area Assessments.
    ${ }^{6}$ See, in particular Waight, M.M., The Implementation of Singapore Mathematics in a Regional School District in Massachusetts:2000-2006, in Remarks to a National Mathematics Advisory Panel. 2006: Cambridge, MA.[14]

[^2]:    ${ }^{7}$ Giving teachers added textbook options, the U.S. Edition of Primary Mathematics (pub. 2003) supplemented metric weights and measures with their US counterparts.

[^3]:    ${ }^{8}$ See The Model Method, Singapore Ministry of Education (2009).
    ${ }^{9}$ Like Massachusetts, all state tests examine mathematics in alignment with their particular curricular standards. The Standards Edition for K-5 Primary Mathematics is fully aligned with California's syllabus, which aligns then closely with MA standards. However, this edition was published only in 2008.
    ${ }^{10}$ Dr. Richard Bisk, professor of mathematics, has become nationally recognized as an expert on Singapore mathematics.
    ${ }^{11}$ Math coaches, a separate instructional position, give on-site guidance and help to a school's math teachers. Since school budgets frequently do not allow for this extra position, a common administrative practice is to designate "lead teachers" to perform similar tasks without extra cost to the school.
    ${ }^{12}$ These teacher leaders also became (and remained for some years) facilitators in Dr. Bisk's professional development classes.

[^4]:    ${ }^{13}$ During school years 1998-1999 and 1999-2000, MCAS tested only grades 4, 8 and 10; 2000-01 to 2004-05, grade 6 tests were added; only since 2005-06 have grades 3 to 8 and 10 been tested.

[^5]:    ${ }^{14}$ District teacher-student records were however incomplete: this data was missing for 2003-04 and 2007-08.

[^6]:    ${ }^{15}$ For example, cohort V4 was tested five times during grades 4 through 8. V4 totaled 1,711 student-trials, ranging from 357 student-trials in 2005 to 345 in 2009.
    ${ }^{16}$ Both raw and scaled mean scores are provided in state reports. Scaled mean scores are described in their Technical Reports, but were not used in this study.

[^7]:    ${ }^{17}$ Scores are raw scores for most grade-years and adjusted scores for 3rd grade scores; only Cohorts V1 and V4 are shown in Figure 3.
    ${ }^{18}$ Regressions are run on adjusted mean scores, while coded adjusted mean scores are shown in Table 9.

[^8]:    ${ }^{19}$ Only 143 students (3\%) have 5 years of CSM.

[^9]:    ${ }^{20}$ The negative sign of t -test statistics is an artifact of coding "no SM " as 0 and " SM " as 1 .
